2009 Washington GIS Conference
May 5, 2009

COMPLIANCE SERVICES INTERNATIONAL

Overview

- Requirement
- Automation overview
- Map development process
- Quality checking procedures
- Process considerations
- Method enhancement possibilities
- Programming considerations
- Map access

Requirement

- Endangered species risk assessment a key requirement in the agrichemical product registration process
- Four key variables:
 - Use site – target for product use, typically a crop
 - Application Method Type
 - Location – a county for the purpose of this example
 - Species – a threatened/endangered species present in the county, according to various species location sources

May be many thousands of permutations, each of which needs a determination and, sometimes, a supporting map

ESRI Map Scripting Capabilities

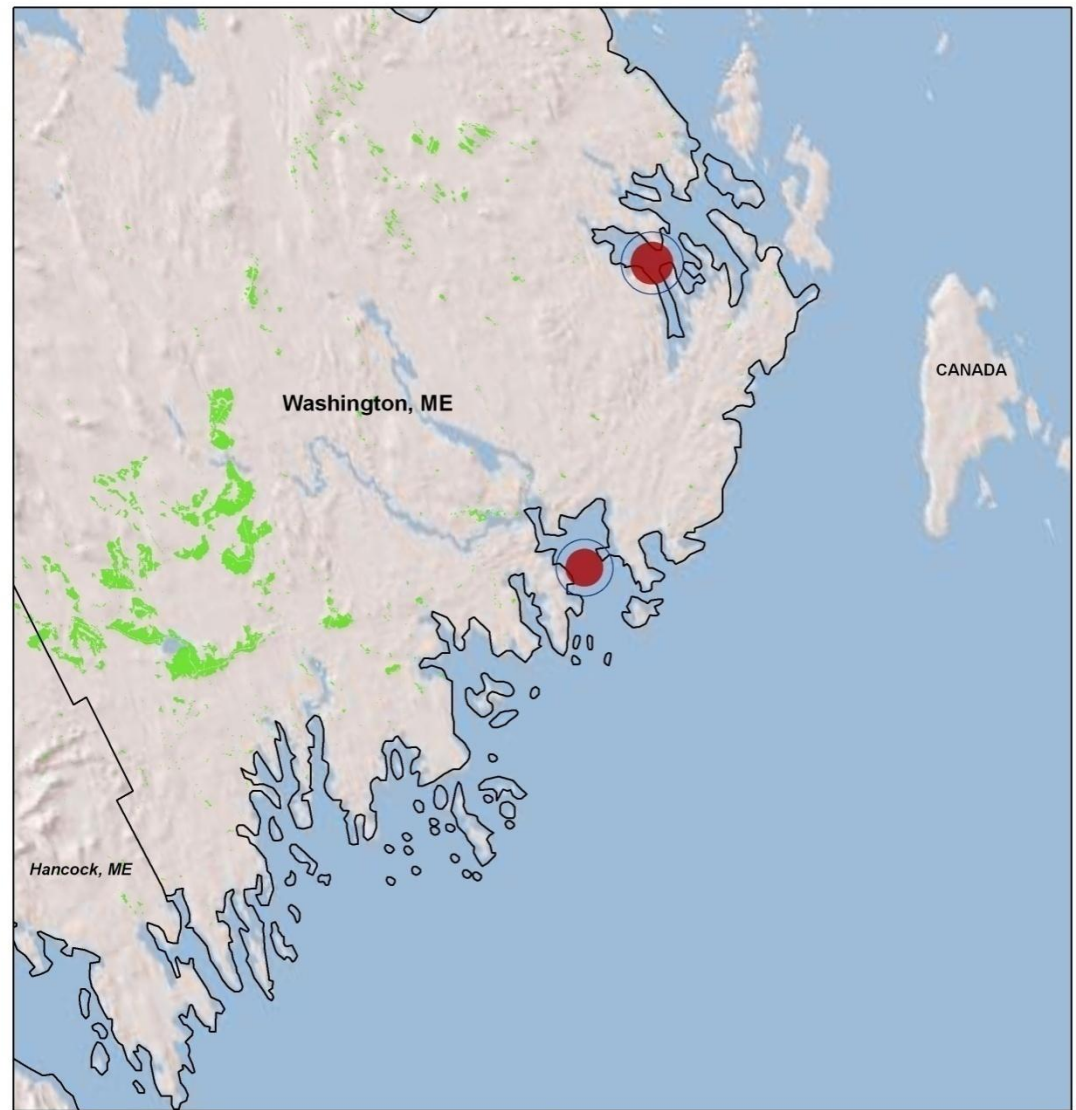

- ArcInfo – Arc Macro Language
Versatile, simple, still widely used
- ArcView 3.x – Avenue
Multiple layouts
- ArcMap/ArcObjects – VBA (Python at 9.4)
One layout per document
- ArcMap/ArcObjects – Many languages
Highly versatile, external development

Automation Concept

- Map automation process analogous to model development
- Develop a set of procedures that use information you pass to them
- Make the input information available
- Set up the process to run efficiently
- Start the process, keep track of progress
- Restart the process as required
- Check the output carefully

Develop Single Map

- Create document
- Add data layers
- Set up layout
- Add/customize
 - map elements
 - graphics elements
- Export map

Roseate tern (*Sterna dougallii dougallii*) - Washington, ME (Two occurrences)

Legend

- Species Occurrence Locators
- Species Occurrences (ARTIFICIAL)
- Counties
- NLCD 2001 Cultivated Crops (Class 82)

County Types

- County of interest: Large label
- Neighboring county: Small label
- Other county: Small label

Note: a species occurrence may be reported by NatureServe as pertaining to the county of interest, but may be physically present in a neighboring county

Projection: North America Albers Equal Area Conic

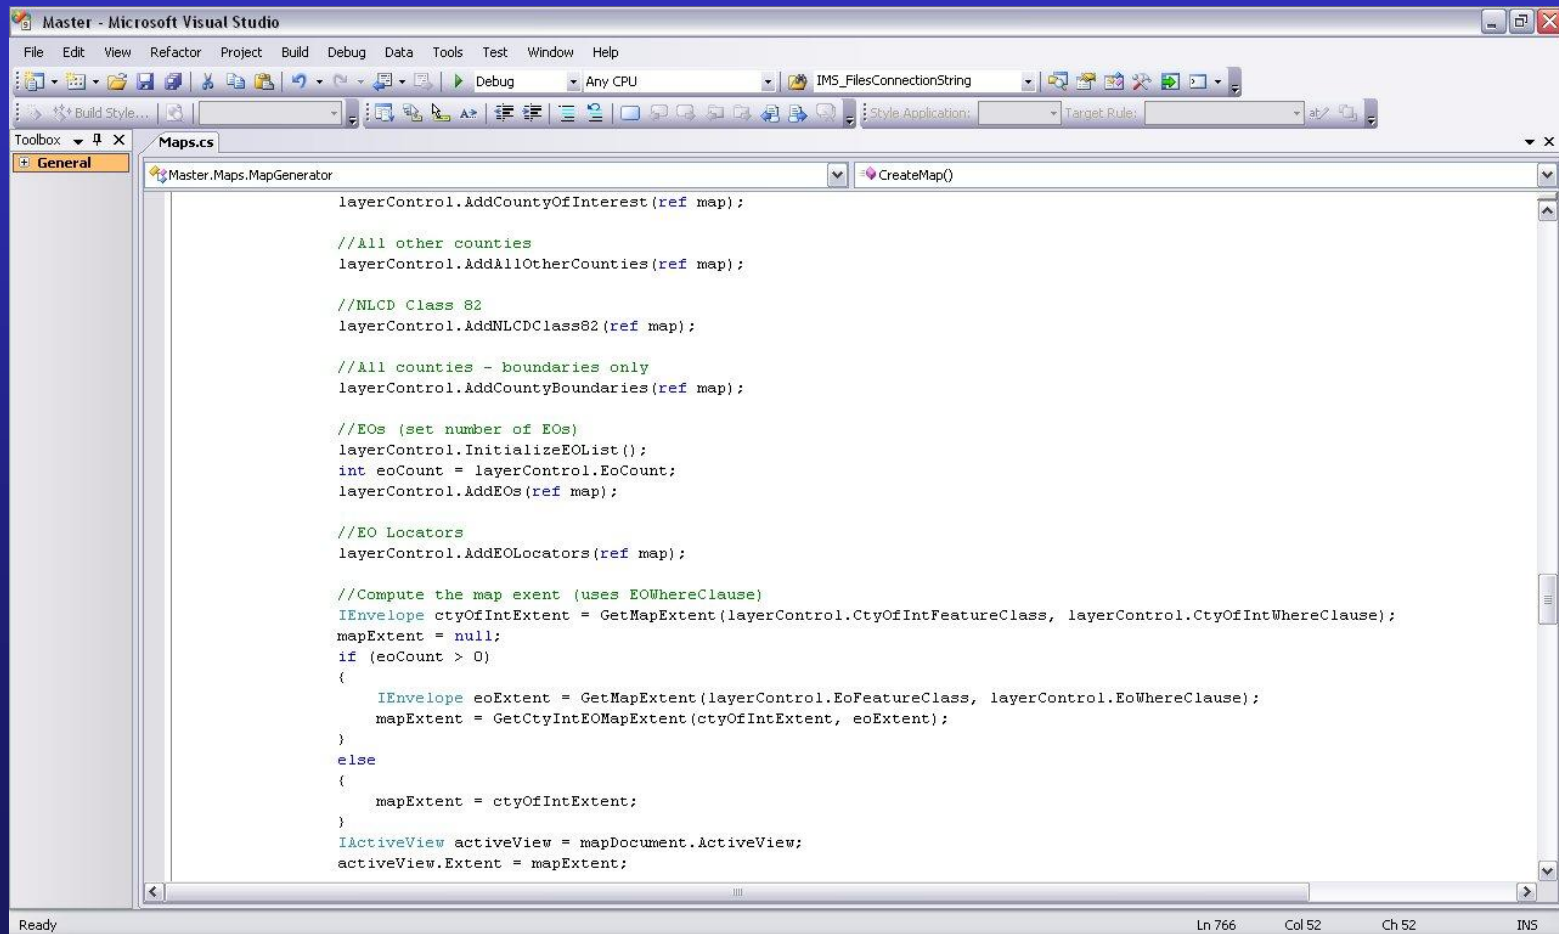

Confidential and Proprietary - For Internal Use Only

Map Development Replication

- Develop code to replicate map creation process
- Could use C#/ArcObjects code to read document properties or just copy/paste properties into code

The screenshot shows the Microsoft Visual Studio IDE with a C# file named 'Maps.cs'. The code is for a 'CreateMap()' method in the 'Master.Maps.MapGenerator' class. The code performs several tasks: it adds various layers to a map control, including counties of interest, all other counties, NLCD Class 82, and county boundaries. It also initializes an EOList, adds EOs, and adds EO locators. Finally, it computes the map extent based on the EOWhereClause and EoFeatureClass, and sets the active view's extent to the computed map extent.

```
layerControl.AddCountyOfInterest (ref map);

//All other counties
layerControl.AddAllOtherCounties (ref map);

//NLCD Class 82
layerControl.AddNLCDClass82 (ref map);

//All counties - boundaries only
layerControl.AddCountyBoundaries (ref map);

//EOs (set number of EOs)
layerControl.InitializeEOList ();
int eoCount = layerControl.EoCount;
layerControl.AddEOs (ref map);

//EO Locators
layerControl.AddEOLocators (ref map);

//Compute the map extent (uses EOWhereClause)
IEnvelope ctyOfIntExtent = GetMapExtent (layerControl.CtyOfIntFeatureClass, layerControl.CtyOfIntWhereClause);
mapExtent = null;
if (eoCount > 0)
{
    IEnvelope eoExtent = GetMapExtent (layerControl.EoFeatureClass, layerControl.EoWhereClause);
    mapExtent = GetCtyIntEOMapExtent (ctyOfIntExtent, eoExtent);
}
else
{
    mapExtent = ctyOfIntExtent;
}
IActiveView activeView = mapDocument.ActiveView;
activeView.Extent = mapExtent;
```

Process Inputs

- Species identifier
 - Species scientific name
 - Species common name
 - Occurrences
- Location identifier
 - State code
 - County name
 - Counties

Fat pocketbook (*Potamilus capax*) - Pike, IL (Three occurrences)

Legend

- Species Occurrence Locators
- Species Occurrences (ARTIFICIAL)
- Counties
- NLCD 2001 Cultivated Crops (Class 82)

County Types

- County of interest: Large label
- Neighboring county: Small label
- Other county: Small label

Note: a species occurrence may be reported by NatureServe as pertaining to the county of interest, but may be physically present in a neighboring county

Projection: North America Albers Equal Area Conic

Iteration Framework

Map ID	Species ID	Location ID	Process Flag	Start Time	End Time
1	54	632	1	4/21/2008 23:35	4/21/2008 23:35
2	2341	781	1	4/21/2008 23:37	4/21/2008 23:52
3	121	63	0	NULL	NULL

- SQL Server table stores
 - Input parameters
 - Process control data
 - Loop over records with process flag = 0
 - Run map process
 - Set process flag = 1 at end of process
 - Continue looping while records are remaining with process flag = 0
- Allows for restarting the process in the event of failures

Map Generation Considerations

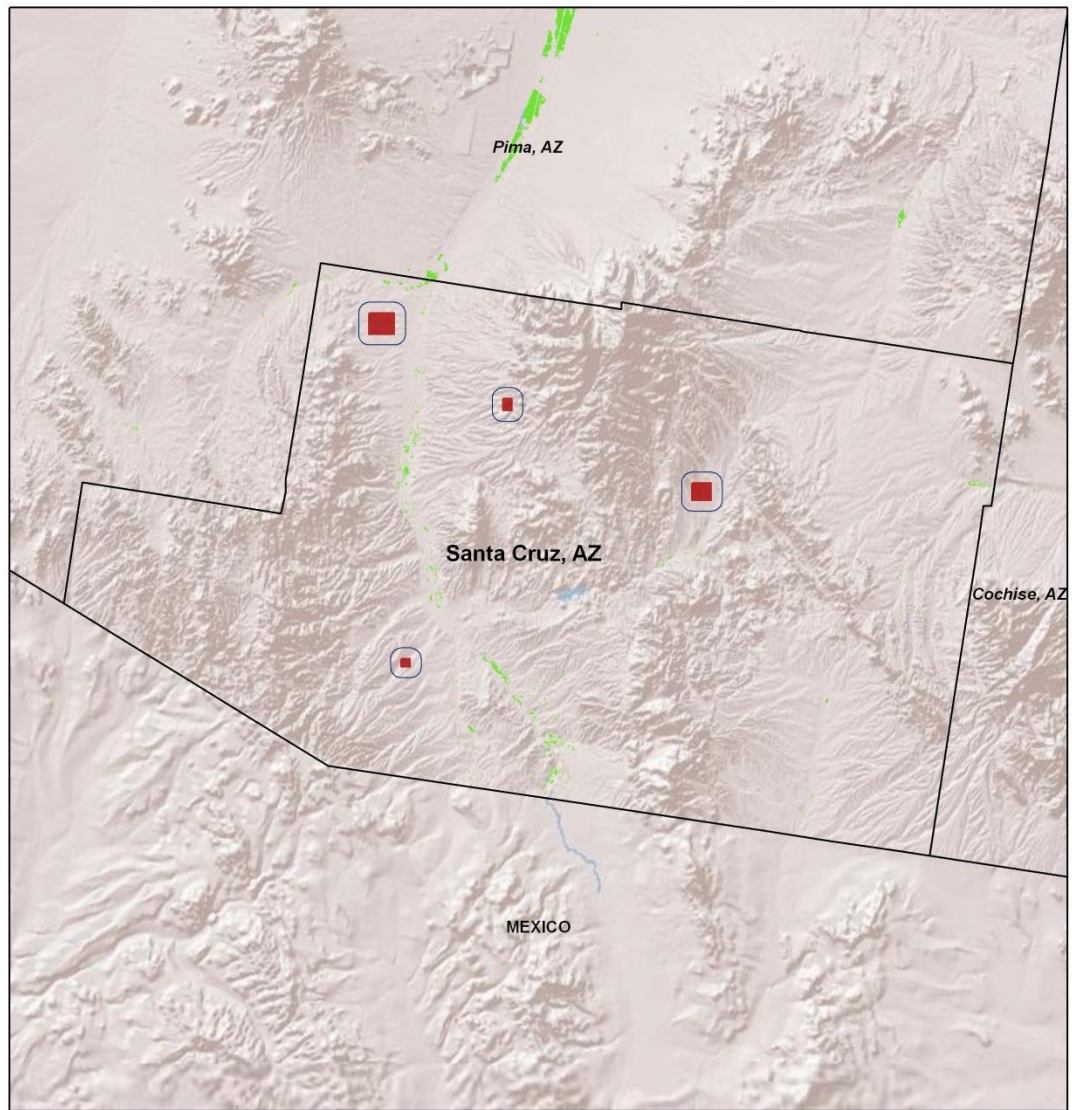

- Variables:
 - Need to define rules for aspects of the map that vary
 - E.g., map extent = bounding rectangle of species locations and counties plus 5 km
- Scale
 - Feature visibility – use locators (1 km buffers)
 - May incorporate scale dependency to hide/show locators
 - Exported image resolution must be such that features don't get distorted and/or disappear

Map Generation Considerations

- Useful information
 - Map extents written to output table for use in an ArcGIS Server website showing similar information
 - May produce locator map(s) showing extents for maps
- Map checking
 - Create a bookmark for map extent

Text Overrun

- Use ScreenDisplay-Class object to check length of string on screen
- Reduce font, test length again
- Repeat as required

Arroyo (=arroyo southwestern) toad (*Bufo californicus (=microscaphus)*) - Santa Cruz, AZ (Four occurrences)

Legend

- Species Occurrence Locators
- Species Occurrences (ARTIFICIAL)
- Counties
- NLCD 2001 Cultivated Crops (Class 82)

County Types

- County of interest: Large label
- Neighboring county: Small label
- Other county: Small label

Note: a species occurrence may be reported by NatureServe as pertaining to the county of interest, but may be physically present in a neighboring county

Projection: North America Albers Equal Area Conic

Compliance Services International, 11/4/08

0 5 10 20 Miles

Map Service Failure

- Use unique color for data frame
- Run code to read image as bitmap
 - Check for data frame color
 - Set process flag to 0 if color present
 - Rerun process if required

alligator, American (*Alligator mississippiensis*) - Issaquena, MS (Four occurrences)

Legend

- Species Occurrence Locators
- Species Occurrences (ARTIFICIAL)
- Counties
- NLCD 2001 Cultivated Crops (Class 82)

County Types

- County of interest: Large label
- Neighboring county: Small label
- Other county: Small label

Note: a species occurrence may be reported by NatureServe as pertaining to the county of interest, but may be physically present in a neighboring county

Projection: North America Albers Equal Area Conic

0 1.5 3 6 Miles

Process Simplification

- Minimize processing requirements
- Break process into small tasks
- Never do the same thing twice (if you can avoid it)
- Consider steps to improve map performance
- Consider ESRI advice for web maps
 - Preprocess layers, if required
 - Use standard projection for all layers

Process Simplification (2)

- Develop re-usable code
- Employ object-based approach
Using coarser objects allows you to bury the more fine-grained ArcObjects code
E.g., text element – much easier to instantiate new text element object than repeat/modify finer code
- Could run process to create map documents first then run separate process to export maps

Trade-off: time required to run process versus effort required to speed things up

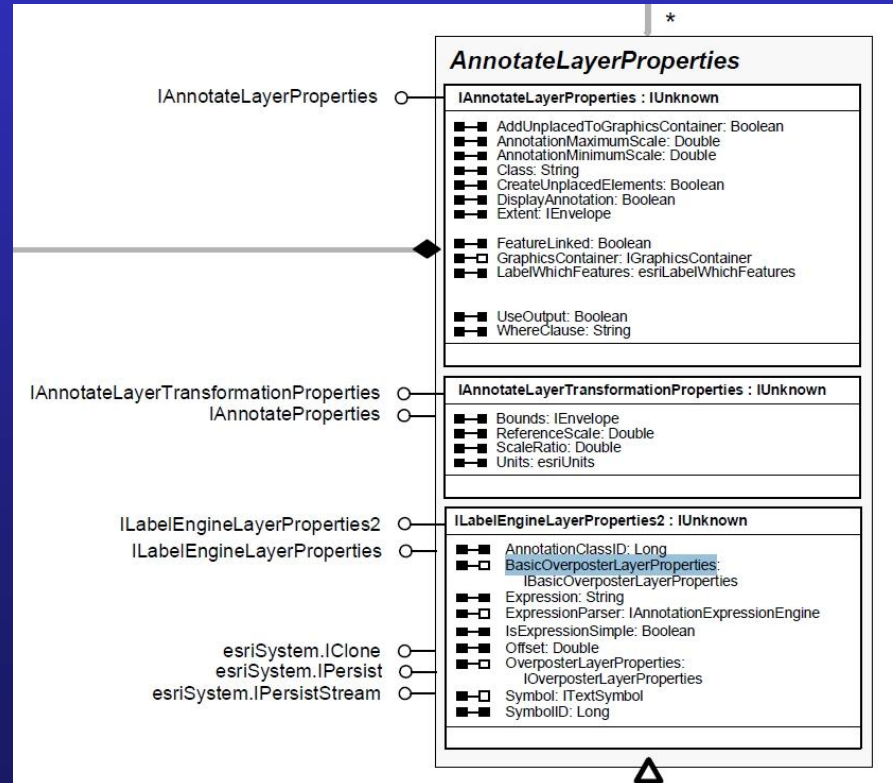

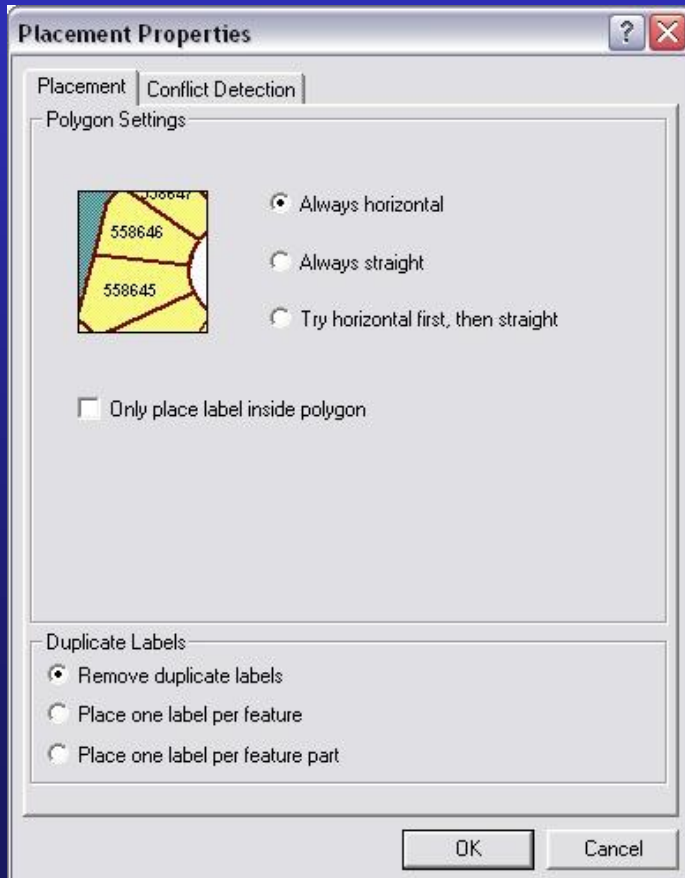

.NET Code Structure

- CreateMaps method
(main loop over species-county pairs)
- Generate map:
 - Map Generator object, CreateMap method
 - Create document
 - Add layers - LayerControl object (get extents)
 - Create a layout, set up data frame, set map extent, create bookmark
 - Add graphics elements
 - SimpleText object
 - NorthArrow object
 - ScaleBar object
 - Bounding rectangle object
- ExportMap

Method Enhancement Possibilities

- Anything you can do in the ArcMap interface, you can do in code

Beware of terminology differences, e.g., remove duplicate labels

`esriBasicNumLabelsOption.esriOneLabelPerName`

Method Enhancement Possibilities (2)

- In current application, maps are independent of one another
- Can easily extend procedure to create a map series (introduce dependencies between maps)
- Use templates
- Set up annotation
- Pre-define layers, read layer files
- Cache map services

Programming Considerations

Memory Management

- Clear resources

Use ReleaseComObject method or set object to null

```
public static void ClearResources(object o)
{
    //http://support.microsoft.com/default.aspx?scid=kb;en-us;317109
    try
    {
        System.Runtime.InteropServices.Marshal.ReleaseComObject(o);
    }
    catch {}
    finally
    {
        o = null;
    }
}
```

- Run separate executable(s)

Programming Considerations

Why .NET?

- Versatility
- Ability to interact with other programs
E.g., insert maps into a Word document or other report format
- Ability to incorporate sophisticated procedures
- Ability to manage memory
- Controllability
- Can develop a control interface (use a form application)

Map Access

- Maps stored in SQL Server database table:
 - Species identifier
 - Location identifier
 - Image
- AJAX-enabled web page
- User selects species and county

When map is requested, image is drawn on screen using .NET graphics capabilities (much faster than using HTML img element)
- Partial refresh of page fast using AJAX

Conclusion

- Microsoft .NET/SQL Server/ESRI ArcObjects technology provides a powerful framework for automated development
- Concepts are applicable to other frameworks
- Let me know if you need help
